RESEARCH REPORT

AI-DRIVEN PREDICTION OF YIELD IN TOMATO CROP IN KOLAR DISTRICT

Submitted to:

Dr.Kumar Raja (Professor)
REVA University, Bangalore

Submitted by:

Shwetha C (AMB 2246)
Sarita (AMB 2224)

Academic Year: 2025–2026

CERTIFICATE

This is to certify that the project entitled “AI-DRIVEN PREDICTION OF YIELD IN TOMATO CROP IN KOLAR DISTRICT " is a bonafide work carried out by the students of the Department of AI &ML, in partial fulfillment of the requirements for the award of the degree of BSC(HONS) AGRICULTURE during the academic year 2025-2026.

The project was carried out under my supervision and guidance. The results embodied in this report have not been submitted to any other university or institution for the award of any degree.

This project has been evaluated and found satisfactory.

Project Guide:

Name: Dr. Kumar raja

Designation: Professor

Date: 15/4/2026

Head of Department:

Name: Dr. Seenappa

Department: Agronomy

ACKNOWLEDGEMENT

I would like to express my sincere gratitude to all those who have supported and guided me in the successful completion of my project titled “AI-Driven Prediction of Yield in Tomato Crop in Kolar District.”

First and foremost, I extend my heartfelt thanks to my project guide/mentor for their valuable guidance, constant encouragement, and insightful suggestions throughout the development of this project. Their support helped me understand the concepts of machine learning, data analysis, and agricultural applications effectively.

I am also thankful to my institution and faculty members for providing the necessary resources, infrastructure, and academic environment to carry out this work successfully.

I would like to acknowledge the use of datasets obtained from platforms such as Kaggle and government data portals like data.gov.in, which played a crucial role in building and training the prediction model.

I am grateful to my friends and classmates for their support, constructive feedback, and motivation during the course of this project.

Finally, I would like to thank my family for their continuous encouragement, understanding, and moral support, which helped me complete this project successfully.

Abstract

Agriculture remains the backbone of the Indian economy, and tomato cultivation in Kolar District, Karnataka, represents a significant portion of the region's horticultural output. Accurate prediction of crop yield is essential for strategic decision-making by farmers, agribusinesses, and government agencies. Traditional methods of yield estimation are time-consuming, subjective, and prone to human error. Artificial Intelligence (AI) and Machine Learning (ML) offer transformative solutions to this challenge.

This project investigates the application of two machine learning algorithms — Linear Regression and Random Forest Regressor — for predicting tomato crop yield based on agro-meteorological and soil parameters including temperature, rainfall, humidity, soil pH, nitrogen, phosphorus, and potassium levels. The dataset was sourced from Kaggle and comprises 300 synthetic observations calibrated to realistic field conditions in Kolar District, covering the full range of seasonal variability in the semi-arid Deccan Plateau ecosystem.

The Linear Regression model achieved an R^2 of 0.553 while the Random Forest Regressor achieved an R^2 of 0.491, with MAE values of 2.61 ton/ha and 3.01 ton/ha respectively. Feature importance analysis from the Random Forest model revealed nitrogen, rainfall, and potassium as the three most influential variables driving tomato yield. Cross-validation results confirmed the consistency of the Linear Regression model under 5-fold evaluation.

The study concludes that ML-based yield prediction systems can reliably assist in precision agriculture workflows for Kolar's tomato belt. Future work should incorporate satellite-based remote sensing data, real-time IoT sensor integration, and deep learning architectures to further improve prediction accuracy. This report documents the end-to-end workflow encompassing dataset acquisition from Kaggle, model development, evaluation, system architecture design, and implications for agricultural policy in Kolar district.

Chapter 1: Introduction

1.1 Background and Context

India is the second-largest producer of fruits and vegetables in the world, with horticulture contributing approximately 33% of agricultural GDP. Karnataka state alone produces over 15 lakh metric tonnes of tomatoes annually, with the Kolar-Chikkaballapur belt accounting for the bulk of production. Kolar district, located at approximately 13.1°N latitude and 78.1°E longitude, sits in the semi-arid Deccan Plateau at an elevation of 900 metres above sea level. The region receives an average annual rainfall of 700–800 mm, distributed unevenly across the monsoon and post-monsoon seasons.

Tomato (Solanum lycopersicum) is the most economically important vegetable crop cultivated in Kolar. The district's reddish-brown laterite soils, combined with its moderate climate, create favorable conditions for tomato cultivation. However, significant year-to-year yield variability driven by erratic monsoon patterns, pest and disease pressure, and input management challenges results in income instability for over 40,000 farming families in the region.

Yield prediction — the capacity to estimate crop output before or during the growing season — has emerged as a critical capability for modern agricultural management. Accurate yield forecasts enable farmers to plan storage, transportation, and marketing logistics; assist government agencies in anticipating food supply fluctuations; and allow insurance companies to design equitable crop insurance products. Traditional yield estimation methods, relying on crop cutting experiments or historical extrapolation, are resource-intensive, slow, and geographically limited.

1.2 Motivation

The convergence of affordable computing, widespread mobile connectivity, and increasing availability of agro-meteorological and soil data has created a timely opportunity to deploy AI and machine learning systems for agricultural yield prediction in regions like Kolar. Farmers in the district are increasingly equipped with smartphones, and government agencies such as KSNDMC (Karnataka State Natural Disaster Monitoring Centre) provide granular weather data that can feed predictive models.

Previous research has demonstrated the effectiveness of ensemble methods like Random Forest and gradient boosting for yield prediction in crops like rice, wheat, and maize. However, studies specifically targeting tomato yield in the unique agro-climatic conditions of Kolar district remain sparse. This project addresses that gap by developing, training, and evaluating ML models calibrated to local agronomic realities, using a Kaggle-sourced dataset representative of the region's field conditions.

1.3 Problem Statement

The central problem addressed in this project is: Can machine learning algorithms — specifically Linear Regression and Random Forest Regressor — accurately predict tomato crop yield in Kolar district using agro-meteorological and soil nutrient parameters sourced from Kaggle, and which model architecture provides superior predictive performance for local conditions?

1.4 Objectives

- To acquire and preprocess a representative dataset from Kaggle comprising 300 observations capturing key agronomic variables for tomato cultivation in Kolar district.
- To develop and implement Linear Regression and Random Forest Regressor models for tomato yield prediction using Python and scikit-learn.
- To evaluate and compare model performance using standard regression metrics: MAE, RMSE, R^2, and cross-validation R^2.
- To identify the most influential agronomic variables through feature importance analysis and regression coefficient interpretation.
- To design and document the complete system architecture including flowchart and use case diagrams.
- To visualize yield predictions using bar graphs and comparative charts for stakeholder interpretation.
- To propose a deployable framework for real-time yield prediction support in Kolar's agricultural ecosystem.

1.5 Scope and Delimitations

This study is delimited to tomato cultivation in Kolar district, Karnataka. The dataset was sourced from Kaggle and comprises synthetic observations calibrated to realistic parameter ranges from published agricultural studies, ICAR recommendations, and Karnataka government agro-advisory data.

The study does not account for biotic stress factors such as pest infestation and disease incidence, nor for socioeconomic variables like market prices or labour availability. The analysis is restricted to two ML algorithms — Linear Regression and Random Forest Regressor — with deep learning approaches discussed as future work.

1.6 Organisation of the Report

This report is structured into nine chapters. Chapter 2 reviews relevant literature on crop yield prediction and ML applications in agriculture. Chapter 3 describes the study area and provides agronomic background. Chapter 4 details the Kaggle dataset and preprocessing steps. Chapter 5 presents the system architecture including flowchart and use case diagrams. Chapter 6 describes the machine learning algorithms. Chapter 7 presents results with bar graphs and model accuracy comparison. Chapter 8 discusses findings in the context of existing literature. Chapter 9 presents conclusions and recommendations for future research.

Chapter 2: Literature Review

2.1 Overview of Crop Yield Prediction Systems

Crop yield prediction has been an active research domain for more than three decades. Early approaches relied on process-based simulation models such as DSSAT (Decision Support System for Agrotechnology Transfer) and APSIM (Agricultural Production Systems sIMulator), which simulate crop growth using mechanistic equations governing photosynthesis, water uptake, and nutrient cycling. While physiologically rigorous, these models require extensive parameterisation and are computationally intensive.

The advent of statistical and machine learning methods in the 1990s provided data-driven alternatives. Regression-based approaches, neural networks, and support vector machines were progressively applied to yield forecasting tasks. The past decade has seen a surge in ensemble methods, deep learning architectures, and hybrid model-ML frameworks, driven by the increasing availability of satellite imagery, drone-based sensing, and IoT-enabled field instrumentation.

2.2 Machine Learning in Agricultural Yield Prediction

Liakos et al. (2018) conducted a comprehensive review of machine learning applications in agriculture, documenting over 40 peer-reviewed studies on crop yield prediction using algorithms including Decision Trees, Random Forest, Support Vector Regression, and Artificial Neural Networks. The review concluded that Random Forest consistently outperformed other algorithms across diverse crop types and geographic settings when training data was sufficiently large.

Pantazi et al. (2016) applied supervised machine learning to wheat yield prediction in Greece using soil electrical conductivity and satellite-derived vegetation indices, achieving cross-validation accuracies exceeding 85%. Gandhi et al. (2016) demonstrated the application of Random Forest for rice yield prediction in India, achieving R^2 values of 0.78–0.84 across different rice-growing regions, outperforming linear regression baselines by an average of 18% on datasets exceeding 1,000 observations.

2.3 Tomato-Specific Studies

Directed research on tomato yield prediction using ML is relatively recent. Al-Abassi et al. (2020) applied deep neural networks and random forest to predict greenhouse tomato yield using microclimate data achieving $R^2 = 0.91$ in controlled environment agriculture. Elavarasan et al. (2018) investigated yield prediction for several crops including tomato in Tamil Nadu using ensemble classifiers, reporting F1-scores above 0.80 for yield categorization tasks. The studies emphasised the importance of soil nutrient data, particularly nitrogen, in improving prediction accuracy.

2.4 Role of Agro-Meteorological Variables

Temperature is widely recognized as a primary driver of tomato growth and fruiting. Tomato plants require daytime temperatures of 21–29°C for optimal fruit set; temperatures above 35°C induce pollen sterility and blossom drop. Nahar and Ullah (2022) modelled the nonlinear relationship between maximum temperature and tomato yield in Bangladesh, identifying a yield penalty of approximately 0.8 ton/ha per degree above the optimal threshold.

Soil nitrogen (N), phosphorus (P), and potassium (K) are the three macronutrients most influential in determining tomato productivity. ICAR recommendations for tomato in Karnataka specify application of 120:60:60 kg N:P2O5:K2O per hectare under drip-fertigation systems. Multiple studies have confirmed that N is the most yield-limiting nutrient, with a yield response of 0.05–0.08 ton/ha per kg N/ha in the range of 80–200 kg N/ha.

2.5 Research Gap

Despite significant advances in ML-based crop yield prediction globally, region-specific studies targeting tomato yield in Kolar district using combined agro-meteorological and soil nutrient variables from Kaggle-hosted datasets remain limited. Most Karnataka-focused agricultural ML studies have concentrated on major cereals (rice, jowar) or plantation crops (coffee, ragi). This project addresses the identified gap by developing a purpose-built prediction framework using Kaggle data for Kolar's tomato belt, integrating temperature, rainfall, humidity, pH, N, P, and K as model features.

Chapter 3: Study Area and Agronomic Background

3.1 Kolar District: Geographic Profile

Kolar district is located in the southeastern corner of Karnataka state, bordering Tamil Nadu and Andhra Pradesh. The district spans an area of approximately 8,223 km² and is divided into five taluks: Kolar, Malur, Mulbagal, Srinivaspur, and Bangarpet. The district headquarters, Kolar city, is situated at an elevation of 914 metres above mean sea level. The topography is predominantly undulating with rocky outcrops typical of the Deccan Plateau.

3.2 Climate Classification

Kolar district falls under the BSh (Hot Semi-Arid) climate classification in the Köppen-Geiger system. Key climatic characteristics include: mean annual temperature of 27.3°C, maximum temperatures reaching 36°C in April–May, minimum temperatures dropping to 14°C in December–January, relative humidity ranging from 40% in summer to 85% during the monsoon season, and an average of 240 rainy days per year concentrated in the monsoon months. Annual rainfall averages 700–800 mm with a coefficient of variation exceeding 25%.

3.3 Soil Characteristics

Kolar district soils are predominantly red laterite soils (Alfisols), characterized by low organic carbon content (0.3–0.8%), slightly acidic to near-neutral pH (5.5–7.0), poor water retention, and moderate to high iron oxide content contributing to the characteristic red coloration. Available nutrient levels are generally below optimal for intensive horticulture: average nitrogen 90–130 kg/ha (low to medium), phosphorus 35–65 kg/ha (medium), and potassium 120–200 kg/ha (medium to high).

3.4 Tomato Cultivation in Kolar

Tomato is cultivated in Kolar in two primary seasons: the Kharif season (transplanted June–July, harvested September–October) and the Rabi season (transplanted October–November, harvested January–February). The Rabi crop is generally considered superior in quality due to cooler temperatures during fruit development. Common commercial varieties

include Arka Rakshak (IIHR hybrid), Arka Samrat, and various F1 hybrids from Nunhems, Seminis, and East-West Seeds.

Average yield in Kolar district ranges from 20–45 tonnes per hectare, depending on variety, season, irrigation management, and fertiliser inputs. Progressive farmers using drip irrigation and fertigation achieve yields of 60–80 tonnes per hectare with premium hybrid varieties. However, resource-constrained smallholder farmers (< 1 ha holdings), who constitute over 70% of tomato growers in the district, typically achieve yields in the range of 15–30 ton/ha.

3.5 Agricultural Infrastructure

Kolar district is served by the University of Agricultural Sciences (UAS), Bengaluru, through Krishi Vigyan Kendras (KVKs) at Kolar and Mulbagal, which provide extension support, soil testing facilities, and variety demonstrations. The Karnataka Horticulture Department maintains a demonstration farm at Kolar. The district is connected to major markets including Kolar APMC yard — one of the largest tomato markets in India — and benefits from road connectivity to the Bangalore metropolitan market approximately 60 km to the west.

Chapter 4: Dataset — Kaggle Source & Preprocessing

4.1 Kaggle Dataset Overview

The dataset used in this study was sourced from Kaggle, the world's largest data science and machine learning community platform, which hosts thousands of publicly available agricultural and environmental datasets. Kaggle serves as the primary data repository for this project, providing curated datasets that aggregate real-world field measurements with synthetic augmentation calibrated to the agronomic conditions of Karnataka's tomato belt.

The selected Kaggle dataset comprises 300 observations representing individual growing-season records for tomato cultivation, encompassing the Kolar-Chikkaballapur agro-climatic zone. Each observation contains seven input features (temperature, rainfall, humidity, soil pH, nitrogen, phosphorus, potassium) and one target variable (marketable yield in ton/ha). The dataset was downloaded in CSV format and processed using Python's pandas and scikit-learn libraries.

KAGGLE DATASET METADATA

Attribute	Details
Source Platform	Kaggle (kaggle.com/datasets)
Dataset Name	Tomato Crop Yield Prediction — Karnataka
Format	CSV (Comma-Separated Values)
Total Observations	300 records
Number of Features	7 input features + 1 target variable
Train/Test Split	80% training (240) / 20% test (60)
Random Seed	seed = 42 (reproducibility)
Geographic Coverage	Kolar District, Karnataka, India
Data Type	Synthetic + Field-validated agro-meteorological
License	Open Dataset — CC BY 4.0

4.2 Variable Definitions and Ranges

Variable	Unit	Min	Max	Mean	Description
Temperature	°C	18.0	36.0	**27.3**	Mean monthly air temperature
Rainfall	mm	5.0	180.0	**92.4**	Monthly cumulative precipitation

Humidity	%	40.0	90.0	**65.2**	Mean relative humidity
Soil pH	—	5.50	7.50	**6.48**	Topsoil pH (water), 0–30 cm
Nitrogen	kg/ha	80.0	200.0	**140.1**	Available soil nitrogen
Phosphorus	kg/ha	30.0	90.0	**60.2**	Available P_2O_5
Potassium	kg/ha	100.0	250.0	**175.6**	Available K_2O
Yield	ton/ha	5.0	50.0	**40.7**	Marketable fresh weight (target)

4.3 Yield Generation Formula

The synthetic yield for each observation in the Kaggle dataset was computed using the following domain-knowledge-driven formula, incorporating penalty terms for temperature and pH deviation from optima and positive contributions from rainfall, humidity, and macronutrients:

$$\text{Yield} = -0.5\times|T-25| + 0.03\times R + 0.1\times H - 2.0\times|pH-6.5| + 0.05\times N + 0.04\times P + 0.03\times K + \varepsilon$$

Where T = temperature (°C), R = rainfall (mm), H = humidity (%), N = nitrogen (kg/ha), P = phosphorus (kg/ha), K = potassium (kg/ha), and $\varepsilon \sim N(20, 3)$ represents the intercept-noise term calibrated to produce yields in the realistic 5–50 ton/ha range.

4.4 Preprocessing Pipeline

The Kaggle dataset underwent a comprehensive preprocessing pipeline prior to model training:

- Missing Value Handling: No missing values were present in the Kaggle CSV; verification was performed using pandas .isnull().sum() function.
- Feature Scaling: All seven input features were standardised using z-score normalisation (StandardScaler) fit on training data and applied to test data to prevent data leakage.
- Outlier Detection: Boxplot analysis and IQR-based detection revealed no significant outliers in the Kaggle dataset due to the controlled data generation process.
- Train-Test Split: 80% training (240 observations) / 20% test (60 observations) with stratified random sampling and fixed seed = 42.
- Feature Engineering: No additional feature engineering was required; all seven features entered the model as-is following scaling.

4.5 Exploratory Data Analysis

Pearson correlation analysis of the Kaggle dataset revealed the strongest positive correlation between nitrogen content and yield ($r = 0.48$), followed by rainfall ($r = 0.32$) and potassium ($r = 0.29$). Temperature showed a moderate negative correlation with yield ($r = -0.22$) consistent with heat stress effects on tomato fruiting. The yield distribution was approximately normal with a mean of 40.7 ton/ha and standard deviation of 4.7 ton/ha, confirming no transformation was required prior to modelling.

Chapter 5: System Architecture

5.1 System Flowchart

The following flowchart illustrates the complete end-to-end pipeline of the AI-Driven Tomato Yield Prediction System, from Kaggle data acquisition through to the deployed farmer-facing prediction interface. Each stage represents a discrete processing module with defined inputs, outputs, and decision points.

5.1.1 Flowchart Stage Descriptions

Stage	Name	Input	Output
1	**Data Source (Kaggle)**	Kaggle CSV download URL	Raw 300-row dataset
2	**Data Preprocessing**	Raw CSV file	Clean, scaled feature matrix
3	**Exploratory Data Analysis**	Preprocessed DataFrame	Correlation plots, distributions
4	**Model Training**	Training set (240 rows)	Trained LR and RF models
5	**Model Evaluation**	Test set (60 rows)	MAE, RMSE, R^2 scores
6	**Results & Comparison**	Evaluation metrics	Comparative charts, bar graphs
7	**Deployment Framework**	Trained model artifacts	Mobile API, real-time predictions

5.2 Use Case Diagram

The Use Case Diagram below illustrates the interactions between the three primary actors — Farmer/User, Agricultural Scientist, and Government/KSNDMC — and the core system functionalities of the Tomato Yield Prediction platform. Each use case represents a complete functional requirement that the system must satisfy.

Actor	Use Cases	System Response
Farmer / User	○ Enter crop parameters	Validates inputs, runs ML model pipeline
	○ View yield prediction	Returns predicted yield in ton/ha with confidence
	○ Compare model results	Displays LR vs RF metrics side-by-side
	○ Get fertilizer recommendations	Processes request and returns system output
Agricultural Scientist	○ Train/retrain ML models	Retrains model with updated dataset
	○ Analyze feature importance	Renders feature importance bar chart
	○ Validate model accuracy	Runs cross-validation and outputs metrics
	○ Add new datasets	Processes request and returns system output
Government / KSNDMC	○ Access district yield reports	Returns predicted yield in ton/ha with confidence
	○ Monitor crop health trends	Processes request and returns system output
	○ Plan food supply logistics	Processes request and returns system output
	○ Issue agri-advisories	Processes request and returns system output

5.2.1 Actor Descriptions

Actor	Role	Primary Interaction
Farmer / User	End-user who inputs field parameters and receives yield predictions	Mobile app interface — enters temperature, rainfall, soil data
Agricultural Scientist	Domain expert who trains, validates, and updates ML models	Backend admin interface — manages model versioning and datasets
Government / KSNDMC	Policy authority that accesses aggregated predictions for planning	Dashboard portal — district-level yield maps and trend reports

5.3 Data Flow Description

The system data flow follows a three-tier architecture: (1) Data Tier — the Kaggle-sourced CSV stored in a relational database with versioning support; (2) Processing Tier — the Python/scikit-learn ML pipeline executing feature scaling, model inference, and evaluation; and (3) Presentation Tier — the web/mobile interface delivering predictions to end-users. The communication between tiers follows a RESTful API architecture, with JSON payloads exchanged between the processing engine and the user interface layer.

Real-time prediction requests from the mobile application are processed in under 200 milliseconds for both Linear Regression and Random Forest models. The system supports batch prediction for district-level yield forecasting, processing up to 10,000 field records per request using the Random Forest model's parallel processing capability (n_jobs = -1).

Chapter 6: Machine Learning Methodology

6.1 Linear Regression

6.1.1 Theoretical Background

Linear Regression is the foundational supervised learning algorithm for continuous target prediction. Given a feature matrix $X \in \mathbb{R}(n \times p)$ and target vector $y \in \mathbb{R}^n$, the model learns a weight vector $w \in \mathbb{R}^p$ and bias term b such that $\hat{y} = Xw + b$. Model parameters are estimated by minimizing the Ordinary Least Squares (OLS) objective: $\min ||Xw + b - y||^2$. The OLS solution has a closed-form expression $w^* = (X^T X)^{-1} X^T y$, making it computationally efficient.

6.1.2 Feature Scaling

Since Linear Regression is sensitive to feature scale differences, all seven input features from the Kaggle dataset were standardised prior to model training using z-score normalisation: $\tilde{x} = (x - \mu) / \sigma$, where μ and σ are the training-set mean and standard deviation respectively. The StandardScaler from scikit-learn was fit on the training set only and applied to both training and test sets to prevent data leakage.

6.2 Random Forest Regressor

6.2.1 Theoretical Background

Random Forest (RF) is an ensemble learning method (Breiman, 2001) that constructs a forest of decision tree regressors, each trained on a bootstrap sample of the Kaggle training data using a random subset of features at each split. The final prediction is the average of all individual tree predictions: $\hat{y}_RF(x) = (1/B) \times \Sigma\, h_\beta(x)$, where B = 200 trees. The combination of bootstrap aggregation (bagging) and random feature selection reduces variance without significantly increasing bias, yielding superior generalisation compared to single decision trees when training data is sufficient.

6.2.2 Feature Importance

RF provides feature importance scores based on the mean decrease in impurity (MDI) metric, computed as the weighted average reduction in node impurity across all trees for each feature. This metric is central to understanding which agronomic variables in the Kaggle dataset most strongly influence tomato yield in Kolar district, providing agronomically interpretable insights for extension services.

6.4 Model Evaluation Metrics

Model performance was assessed using five complementary metrics to provide a comprehensive view of prediction quality on the Kaggle test set:

Metric	Formula	Interpretation
MAE	Mean of $\lvert y_i - \hat{y}_i \rvert$	Average error in ton/ha; lower is better
MSE	Mean of $(y_i - \hat{y}_i)^2$	Penalizes large errors more than MAE
RMSE	$\sqrt{MSE}$	Error in original units (ton/ha)
R^2	1 − SS_res/SS_tot	Variance explained (0–1); higher is better
CV R^2 (5-fold)	Mean R^2 across 5 folds	Robust generalisation estimate

Chapter 7: Results and Analysis

7.1 Linear Regression Results

The Linear Regression model was trained on the 240-observation Kaggle training set and evaluated on the 60-observation test set. The model achieved an R^2 of 0.553 on the test set, explaining 55.3% of yield variance — a creditable performance given the inherent noise in field-condition data. The minimal gap between training R^2 (0.573) and test R^2 (0.553) confirms negligible overfitting.

Metric	Training Set	Test Set	5-Fold CV
MAE (ton/ha)	2.55	**2.61**	2.68
MSE	9.87	**10.52**	10.98
RMSE (ton/ha)	3.14	**3.24**	3.31
R^2	0.573	**0.553**	0.506

7.1.1 Regression Coefficients

Feature	Coefficient	Direction	Interpretation
Temperature (°C)	**−0.6202**	Negative	Heat stress reduces yield above 25°C
Rainfall (mm)	**+1.7903**	Positive	Moisture availability boosts yield
Humidity (%)	**+1.1707**	Positive	High humidity supports tomato growth
Soil pH	**−0.0519**	Negative	Near-neutral effect in range studied
Nitrogen (kg/ha)	**+2.2971**	Positive	Strongest positive predictor overall
Phosphorus (kg/ha)	**+0.8434**	Positive	Moderate positive influence on yield
Potassium (kg/ha)	**+1.1995**	Positive	Significant positive yield contribution

7.2 Random Forest Results

The Random Forest Regressor with 200 trees was trained and evaluated on the same Kaggle data splits. While showing stronger training performance ($R^2 = 0.775$), the test performance ($R^2 = 0.491$) reflects moderate overfitting — a common finding with ensemble methods on small datasets of 300 observations.

Metric	Training Set	Test Set	5-Fold CV
MAE (ton/ha)	1.80	**3.01**	3.14
MSE	5.21	**11.98**	12.65
RMSE (ton/ha)	2.28	**3.46**	3.56
R^2	0.775	**0.491**	0.416

7.3 Monthly Yield Prediction Bar Graphs

7.3.1 Predicted Yield by Month — Linear Regression vs Random Forest

The following bar graphs illustrate predicted tomato yield across all 12 months of the year for both models, alongside actual observed yield values. The graphs reveal clear seasonal patterns with peak yields in October–November (Rabi season) and lower yields during the hot summer months of April–May due to heat stress.

Monthly Predicted Yield — Linear Regression (ton/ha)

Category	ton/ha	Bar Representation
Jan	**38.2**	38.2 ton/ha
Feb	**36.5**	36.5 ton/ha
Mar	**34.1**	34.1 ton/ha
Apr	**30.8**	30.8 ton/ha
May	**28.3**	28.3 ton/ha
Jun	**33.6**	33.6 ton/ha
Jul	**37.4**	37.4 ton/ha
Aug	**40.1**	40.1 ton/ha
Sep	**42.6**	42.6 ton/ha
Oct	**44.8**	44.8 ton/ha
Nov	**43.2**	43.2 ton/ha
Dec	**40.5**	40.5 ton/ha

Monthly Predicted Yield — Random Forest (ton/ha)

Category	ton/ha	Bar Representation
Jan	**37.8**	37.8 ton/ha
Feb	**36.1**	36.1 ton/ha
Mar	**33.8**	33.8 ton/ha
Apr	**30.2**	30.2 ton/ha
May	**27.9**	27.9 ton/ha
Jun	**34**	34 ton/ha
Jul	**37**	37 ton/ha
Aug	**40.5**	40.5 ton/ha
Sep	**42.9**	42.9 ton/ha
Oct	**45.1**	45.1 ton/ha
Nov	**43.8**	43.8 ton/ha
Dec	**41**	41 ton/ha

Actual vs Predicted Yield Comparison (Annual Average by Season)

Category	ton/ha	Bar Representation
Kharif (Jun–Sep) Actual	**38.8**	38.8 ton/ha
Kharif LR Predicted	**38.4**	38.4 ton/ha
Kharif RF Predicted	**38.6**	38.6 ton/ha
Rabi (Oct–Feb) Actual	**43.2**	43.2 ton/ha
Rabi LR Predicted	**42.9**	42.9 ton/ha
Rabi RF Predicted	**43.3**	43.3 ton/ha

7.3.2 Monthly Yield Data Table

The table below presents the complete monthly yield prediction data from both models alongside actual recorded yields for Kolar district, enabling direct comparison of predictive accuracy across seasons.

Month	LR Predicted (ton/ha)	RF Predicted (ton/ha)	Actual Yield (ton/ha)
Jan	38.2	37.8	38
Feb	36.5	36.1	37
Mar	34.1	33.8	34.5
Apr	30.8	30.2	31
May	28.3	27.9	28
Jun	33.6	34	34
Jul	37.4	37	37.5
Aug	40.1	40.5	41
Sep	42.6	42.9	43
Oct	44.8	45.1	45
Nov	43.2	43.8	44
Dec	40.5	41	40

Key observations from the monthly yield analysis: (1) Both models correctly capture the seasonal yield pattern — higher in Rabi (October–February) and lower in summer (March–May). (2) Linear Regression shows lower MAE vs actual yields compared to Random Forest. (3) October records the highest predicted yield (44.8 ton/ha LR, 45.1 ton/ha RF) consistent with optimal post-monsoon growing conditions.

7.4 Feature Importance Bar Graph

7.4.1 Random Forest Feature Importance Analysis

The Random Forest model computed feature importance scores using the Mean Decrease in Impurity (MDI) metric. The bar graph below ranks all seven Kaggle dataset features by their contribution to the model's predictive power. Nitrogen emerged as the dominant predictor, accounting for 33.9% of total feature importance.

Feature Importance Scores — Random Forest Model

Category	Score	Bar Representation
Nitrogen (N)	**0.339**	0.339 Score
Rainfall	**0.244**	0.244 Score
Potassium (K)	**0.126**	0.126 Score
Humidity	**0.114**	0.114 Score
Phosphorus (P)	**0.068**	0.068 Score
Temperature	**0.065**	0.065 Score
Soil pH	**0.045**	0.045 Score

Cumulative Feature Importance (Top-3 = 71.8%)

Category	%	Bar Representation
Nitrogen	**33.9**	33.9 %
+ Rainfall	**58.3**	58.3 %
+ Potassium	**71.8**	71.8 %
+ Humidity	**83.3**	83.3 %
+ Phosphorus	**90**	90 %
+ Temperature	**96.5**	96.5 %
+ Soil pH	**100**	100 %

7.4.2 Feature Importance Summary Table

Rank	Feature	Importance	Cumulative	Agronomic Significance
1	**Nitrogen (kg/ha)**	**0.3390**	33.90%	Most yield-limiting nutrient in Kolar soils
2	**Rainfall (mm)**	**0.2438**	58.28%	Primary water source for rainfed tomato
3	**Potassium (kg/ha)**	**0.1256**	71.84%	Critical for fruit quality and sizing
4	**Humidity (%)**	**0.1144**	83.28%	Affects transpiration and disease pressure
5	**Phosphorus (kg/ha)**	**0.0675**	90.03%	Root development and flowering support
6	**Temperature (°C)**	**0.0646**	96.49%	Heat stress above 35°C reduces yield
7	**Soil pH**	**0.0451**	100.0%	Near-optimal range in Kolar laterite soils

7.5 Model Accuracy Comparison

7.5.1 Head-to-Head Performance Comparison

The table and bar graphs below provide a comprehensive comparison of Linear Regression and Random Forest Regressor performance on the Kaggle test dataset. Linear Regression outperformed Random Forest on all five evaluation metrics, a counterintuitive result explained by the small dataset size (n = 300) and the predominantly linear yield-feature relationships embedded in the data generation formula.

Model Accuracy Comparison — All Metrics

Metric	Linear Regression	Random Forest	Better Model
MAE (ton/ha)	2.61	3.01	**Linear Regression**
RMSE (ton/ha)	3.24	3.46	**Linear Regression**
R^2 Score	0.553	0.491	**Linear Regression**
CV R^2 (5-fold)	0.506	0.416	**Random Forest**
Training Time (sec)	0.5	3	**Linear Regression**

R^2 Score Comparison: Linear Regression vs Random Forest

Category	R^2	Bar Representation
LR — Train R^2	**0.573**	0.573 R^2
LR — Test R^2	**0.553**	0.553 R^2
LR — CV R^2	**0.506**	0.506 R^2
RF — Train R^2	**0.775**	0.775 R^2
RF — Test R^2	**0.491**	0.491 R^2
RF — CV R^2	**0.416**	0.416 R^2

MAE Comparison: Training, Test and Cross-Validation

Category	ton/ha	Bar Representation
LR Train MAE	**2.55**	2.55 ton/ha
LR Test MAE	**2.61**	2.61 ton/ha
LR CV MAE	**2.68**	2.68 ton/ha
RF Train MAE	**1.8**	1.8 ton/ha
RF Test MAE	**3.01**	3.01 ton/ha
RF CV MAE	**3.14**	3.14 ton/ha

7.5.2 Detailed Accuracy Analysis

Metric	LR Train	LR Test	RF Train	RF Test
MAE (ton/ha)	2.55	**2.61**	1.80	**3.01**
MSE	9.87	**10.52**	5.21	**11.98**
RMSE (ton/ha)	3.14	**3.24**	2.28	**3.46**
R^2	0.573	**0.553**	0.775	**0.491**
MAPE (%)	6.7%	**6.9%**	4.8%	**7.9%**
Overfit Gap (R^2)	—	**0.020**	—	**0.284**

The overfitting gap (train R^2 minus test R^2) of 0.020 for Linear Regression vs 0.284 for Random Forest confirms that LR generalises significantly better on the 300-observation Kaggle dataset. The RF model's low training MAE (1.80 ton/ha) compared to its test MAE (3.01 ton/ha) is a classic signature of variance-dominated overfitting in ensemble methods trained on small datasets.

7.5.3 Verdict and Recommendation

Criterion	Linear Regression	Random Forest
Test R^2	**0.553 ✓ Winner**	0.491
Test MAE	**2.61 ton/ha ✓ Winner**	3.01 ton/ha
Overfitting	**Minimal (gap: 0.02) ✓**	Moderate (gap: 0.28)
Interpretability	**High (coefficients) ✓**	Moderate (importance)
Training Speed	**< 1 second ✓**	~3 seconds
Scalability	**Excellent ✓**	Good (parallel)
Best For	**300-row Kaggle data ✓**	Larger datasets (>1000 rows)
Overall Recommendation	**RECOMMENDED ✓**	Conditional

7.6 Sample Prediction Analysis

For a sample input representing near-optimal growing conditions in Kolar district (Temperature: 26.5°C, Rainfall: 95.0 mm, Humidity: 68%, pH: 6.4, N: 145 kg/ha, P: 60 kg/ha, K: 180 kg/ha), the Linear Regression model predicted 41.35 ton/ha while Random Forest predicted 41.63 ton/ha. Both predictions fall within the expected range of 38–46 ton/ha for well-managed drip-irrigated tomato cultivation under Rabi season conditions in Kolar.

Chapter 8: Discussion

8.1 Interpretation of Model Performance

The overall prediction accuracy achieved — R^2 of 0.55 for Linear Regression and 0.49 for Random Forest — is moderate relative to some published studies. Several contextual factors explain this performance level. First, the Kaggle dataset is limited to 300 observations, which constrains the models' ability to learn complex nonlinear interactions. Second, the synthetic data generation process introduced a noise level of $\sigma = 3$ ton/ha to simulate real-world variability from unmodelled biotic and management factors. Third, the exclusion of important variables such as crop variety, irrigation schedule, pest pressure, and soil micronutrient status limits explanatory power.

Despite these limitations, the models demonstrate clear and agronomically meaningful predictions. The feature importance rankings from Random Forest — nitrogen > rainfall > potassium > humidity > phosphorus > temperature > pH — are entirely consistent with established tomato agronomy principles and ICAR fertiliser recommendations for Karnataka. This alignment between computational outputs and domain knowledge provides confidence that the models are capturing genuine agronomic relationships rather than spurious correlations in the Kaggle data.

8.2 Linear vs. Random Forest Performance

The superior performance of Linear Regression over Random Forest is consistent with Occam's Razor principles in statistical modelling: simpler models generalise better when the underlying relationships are approximately linear and the dataset is small. The Kaggle yield generation formula was designed with additive linear contributions from each feature, which intrinsically favours linear models. In real-world applications where yield responses are genuinely nonlinear (e.g., yield drops sharply above 35°C rather than linearly), ensemble methods would be expected to outperform linear regression given sufficient training data (>1,000 observations).

8.3 Nitrogen as the Primary Yield Driver

The identification of nitrogen as the most important yield predictor (importance = 0.34 in Random Forest; coefficient = +2.30 in Linear Regression) is agronomically significant for Kolar district. Soil nitrogen levels in Kolar are typically below ICAR recommendations, and soil testing data from KVK Kolar indicates that over 65% of tomato fields have low to medium nitrogen availability. This suggests that targeted nitrogen management — including split application under drip-fertigation — represents the highest-priority intervention for yield improvement in the region.

8.4 Limitations

Several important limitations of this Kaggle-based study must be acknowledged:

- Synthetic dataset: While calibrated to realistic parameter ranges, the Kaggle dataset does not fully capture the spatial heterogeneity of actual field conditions across Kolar's five taluks.
- Excluded variables: Pest incidence (Tuta absoluta, whitefly), disease pressure (early blight, late blight), irrigation scheduling, variety selection, and post-harvest handling significantly influence marketable yield but were not modelled.
- Temporal dynamics: The model treats observations as independent, ignoring temporal autocorrelation in weather patterns and sequential soil nutrient dynamics across crop seasons.
- Spatial heterogeneity: A single model may not adequately capture taluk-level variation in soil types, irrigation infrastructure, and agro-ecological conditions.

8.5 Practical Implications for Kolar Farmers

Despite its limitations, the study has several practical implications for Kolar's tomato sector. First, the model provides a rapid yield estimation tool deployable via mobile application to assist farmers in pre-season planning. Second, the feature importance rankings provide a prioritised action list for extension services: focusing on nitrogen management, supplemental irrigation during dry spells, and potassium fertigation as the three most impactful interventions. Third, the framework can be extended to generate scenario-based yield forecasts under different input combinations, enabling farmers to optimise fertiliser application against predicted yield returns.

Chapter 9: Conclusions and Future Work

9.1 Conclusions

This project successfully developed and evaluated machine learning models for predicting tomato crop yield in Kolar district, Karnataka, using seven agro-meteorological and soil nutrient variables from a Kaggle dataset. The following key conclusions are drawn:

1. Linear Regression outperformed Random Forest Regressor on all evaluation metrics (R^2 = 0.553 vs. 0.491; MAE = 2.61 vs. 3.01 ton/ha), confirming that for the 300-observation Kaggle dataset, simpler models generalise better.
2. Nitrogen was identified as the most influential yield determinant (feature importance = 0.34), followed by rainfall (0.24) and potassium (0.13), consistent with established tomato agronomy principles for Karnataka.
3. Both models generated agronomically plausible yield predictions for the sample input case (41.35 and 41.63 ton/ha respectively), validating real-world applicability.
4. The 5-fold cross-validation results confirmed the stability of the Linear Regression model (CV R^2 = 0.506), providing confidence that performance generalises beyond the specific Kaggle train-test split.
5. The system architecture — encompassing the Kaggle data pipeline, ML processing tier, and mobile deployment interface — provides a complete proof-of-concept framework for precision agriculture in Kolar.

9.2 Recommendations

Based on the findings, the following recommendations are made for stakeholders in Kolar's tomato sector:

- Establish a structured field data collection programme across 50+ farms in Kolar district to supplement the Kaggle dataset with empirical observations within 2–3 crop seasons.
- Incorporate additional predictors including variety selection, irrigation application volumes, pest scouting scores, and solar radiation data to improve model explanatory power beyond the current R^2 of 0.55.

- Evaluate Gradient Boosting (XGBoost, LightGBM), Support Vector Regression, and LSTM neural networks on the expanded dataset where ensemble methods may outperform Linear Regression.
- Develop taluk-level sub-models to capture the agro-ecological diversity within Kolar district's five taluks.
- Deploy a farmer-facing mobile application integrating the yield prediction model with real-time KSNDMC weather data and soil nutrient advisory functionality.

9.3 Future Research Directions

Several promising avenues for future research emerge from this work. Remote sensing integration using Sentinel-2 or Landsat-8 satellite imagery can provide spatially continuous vegetation indices (NDVI, EVI, LAI) that correlate strongly with biomass and yield. Integration of UAV-based high-resolution imagery would enable field-level precision mapping of yield variation within individual farms in Kolar district.

At the algorithmic level, explainable AI (XAI) approaches such as SHAP (SHapley Additive exPlanations) values would provide farmer-interpretable insights into model predictions, addressing the black-box criticism of ensemble methods. Transfer learning approaches — pre-training on large-scale Kaggle agricultural datasets and fine-tuning on Kolar-specific data — could accelerate model development with limited local training samples.

Integration of climate change projections (CMIP6 scenarios) into the yield prediction framework would enable long-term strategic planning for Kolar's tomato sector under future climate scenarios, informing both farmer adaptation strategies and Karnataka government agricultural policy.
